

PRP for Erectile Dysfunction or the P-Shot

Where Did the Name P-Shot® Come From?

The name P-Shot® is actually a shortened version for the Priapus Shot®. It was coined by Dr. Charles Runels after he first injected his own penis. He felt that Priapus, the Greek god of male regenerative power, perfectly represented what he was trying to achieve.

What Benefits Can a Man Have from the P-Shot®?

- Stronger, firmer erections
- Easier to achieve and maintain erections (i.e., improved sexual stamina)
- Increased penile length and girth
- Improvement in or resolution of penile curvature from Peyronie's Disease
- Resolution of penile pain with erection
- Increased sensitivity in the penis
- Better overall blood flow to the penis

Is the P-Shot® the Same Thing as Trimix Injections?

No. TriMix is a shot to produce an erection for a brief period of time and must be given every time you wish to have an erection; however, the P-Shot® is a treatment that revives and enhances your natural erections.

How Does the P-Shot® Work?

The growth factors & proteins released by the high concentration of platelets in PRP in turn activate - if any - stem cells and stimulate cellular repair and regeneration wherever they are applied in the body. In addition, collagen production and the formation of new blood vessels occurs and further aids in tissue repair.

What Are the Potential Side Effects of the P-Shot®?

Since PRP is extracted from your own blood, there are few and only minor potential side effects. These include minor bleeding or bruising, swelling, and very rarely infection.
